Consultant Pathologist

Report of a case
A 42 year old Bahraini woman presented with history of recurrent skin lesions over legs, forearms, arms and upper back of seventeen years duration. The lesions were asymptomatic and healed with depressed scar. Several previous attempts at treatment had been unsuccessful. She had suffered from insulin dependent diabetes mellitus since the age of 25 years.

Cutaneous examination revealed multiple erythematous nodules and plaques distributed over forearms, dorsa of hands, arms, upper back and left thigh (Fig. 1). Lesion over left wrist was annular, with central clearance (fig-2). There was a hypopigmented, depressed scar over left forearm (fig-1). General examination was J. Dermatol Treat 2001; 12:135-139.

within normal limits. Fasting blood sugar was 7.4 mmol/L (normal 3.6-5.8 mmol/L). HbA1c level was 8% (normal 4.3-5.8%). Other routine investigations were within normal limits.

Biopsy was performed from the lesion on the right hand. (Fig-3,4).

What is your diagnosis?
Answer: Necrobiosis lipoidicadiabeticorum (NLD)
Microscopic findings: Epidermis was atrophic. Dermis showed areas of necrobiosis, characterized by altered collagen, which appeared homogenous, splintered, and with loss of nuclei (fig-3). Alternating with these areas of necrobiosis, there were areas of cellular infiltration around blood vessels, composed of lymphocytes, histiocytes and foreign body giant cells (fig-4). Some giant cells contained refractile bodies. Few foam cells were also seen. Verhoeff stain for elastic tissue showed fragmentation of elastic fibres. Blood vessels showed prominent endothelial cells. These changes were present through out dermis.

Course: Patient has been treated with several treatments, including local steroids, chloroquine and PUVA therapy, with out significant benefit.

1. Clinical photograph showing multiple erythematous nodules and plaques over upper limbs.

2. Clinical photograph showing erythematous nodule and annular plaque over left forearm and wrist. There is a depressed scar over upper forearm.
Discussion:

Necrobiosis lipoidica is a chronic condition, characterized by yellowish atrophic plaques distributed over shins, common in women and often associated with diabetes mellitus. The lesion starts as an erythematous fleshy nodule, which slowly expands to form a yellowish-brown plaque with irregular outline, which may become atrophic. The lesion may ulcerate and healing may occur with the formation of an atrophic scar. Though classically distributed over legs, lesions can occur over other areas, such as forearms, arms, back, chest, and rarely, scalp, nipple and glans penis. The lesions in these atypical locations are often annular. It has been reported that such atypical distribution is not associated with diabetes mellitus. Other clinical variants include NLD with comedones, granuloma annulare like and diffuse variant of NLD. A high degree of awareness is necessary for diagnosis of these atypical lesions.

Histological features: Epidermis is often atrophic. Transepidermal elimination (which appears clinically as comedonal lesions) of elastic fibres and cholesterol crystals have been reported. Dermal pattern may be of two types; a necrotic type and a granulomatous type. The former shows areas of necrobiosis, seen as splintered, homogenous staining collagen, often without nuclei. Areas of necrobiosis may also contain mucin, which stains with alcian blue. In addition there is an infiltrate of lymphoid cells, histiocytes, fibroblasts. Elastic fibres may show degeneration. Blood vessels show prominent endothelial cells with mild thickening of vessel walls. PAS positive, diastase resistant material is often seen around blood vessels, suggesting the deposition of fibrin. Granulomatous pattern, reported more often in lesions over atypical sites, shows focal collection of mononuclear cells, foreign body giant cells, and often foam cells. Giant cells may contain refractile material. Lesions with prominent granulomatous reaction are thought to be less often associated with diabetes mellitus and have been referred to as Granuloma disciformis of Meisner.

The pathogenesis of the condition is poorly understood. Several studies have demonstrated the association of this condition with diabetes mellitus (both insulin dependent and noninsulin-dependent types) and with impaired glucose tolerance. However, the association is highly variable and a significant percentage of patients do not have diabetes mellitus. It has been reported that presence of necrobiosis lipoidica in patients with type 1 diabetes mellitus may signify risk for retinopathy and nephropathy. It has also been suggested that the collagen changes are secondary to vascular changes found in diabetes. Abnormal glycation and glycoxidation of collagen may also contribute to the pathogenesis. Demonstration of immunoglobulins...
complement, and fibrin by direct immunofluorescence in the vessel walls suggests an underlying immunological mechanism. Treatment of the condition is unsatisfactory. Several treatments, such as local and intralesional steroids, hyperbaric oxygen, and local tretinoin have been tried. Systemic drugs reported to be of benefit include steroids, pentoxifylline, and cyclosporin. There is no correlation of disease activity with control of hypoglycemia in cases associated with diabetes.

The Gulf Journal Of Dermatology and Venereology is published biannually by The League Of Dermatologists in the G.C.C. States, and will accept original articles on different fields of Dermatology, STD's and Andrology.

**Manuscripts**

* Should be addressed to the Editor, Dr. Hassan Al Abdulla, P.O. Box 3050, Hamad Medical Corporation, Doha, Qatar. Fax: (+974) 393058

* Two copies of all elements of the paper are requested. All the matter should be typed, double-spaced with wide margins, on one side of each sheet only.

* The paper should have the following arrangement: 1. Title page; 2. Abstracts; 3. Text; 4. References; 5. Legends; 6. Tables; 7. Figures and 8. Arabic summary of the abstract and title if possible. Title page should bear the author(s) name(s), degrees, affiliation(s), and the address to which reprints are to be sent.

**Tables and Figures**

* Refer to figures as Fig. and give Arabic numeral.

* Submit 2 copies of each photograph and drawing on glossy paper of good quality.

* Use black ink for charts (line drawings).

* Identify figures on back by author's name and number of figure.

* Start tables at top of new page.

**References**

* All references in text must be identified by superscript Arabic numerals in the order in which they appear in the manuscript. When referring to a reference, type the last name of the author followed by its reference number. If referring to two authors, use both last names, otherwise type the last name of first author followed by "et al".

* In Reference page, list the references in order of appearance in the manuscript. When referring to a periodical type last name followed by initials, title of paper, periodical name abbreviated as in the original one, year of publication, volume, pages. Type all authors if 3 or less, otherwise type the first 3 authors followed by "et al." e.g. Breathnach AS, Wylie LM. Electron microscopy of melanocytes and melanosomes in freckled human epidermis. J Invest Dermatol 1964;42:389-394. When referring to books, type name of author(s) (as above), title, edition, place, publisher, year, page referring to. e.g. Mckusick VA. Mendelian inheritance in man. 7th Ed. Baltimore: John Hopkins University, 1986: 1228. If the book has contributors, type the name of author(s), title, in: e&ors, title of book, place, publisher, year, page referred to e.g. Vickers CF. Topical corticosteroids. In: Fitzpatrick TB, Eisen AZ, Wolff K, et al. eds. Dermatology in general medicine. New York: McGraw-Hill, 1987: 2540-2545.

* If manuscripts are prepared on IBM PC or compatible computer using word for windows, a 3-1/2 or 5-1/4 inch diskette copy of the article will be appreciated by the publisher.
